

Comparing space point modes.

Henrik Lindahl, Carl Zeiss AB

Carl Zeiss.
Passion to Win.

— Nominal surface

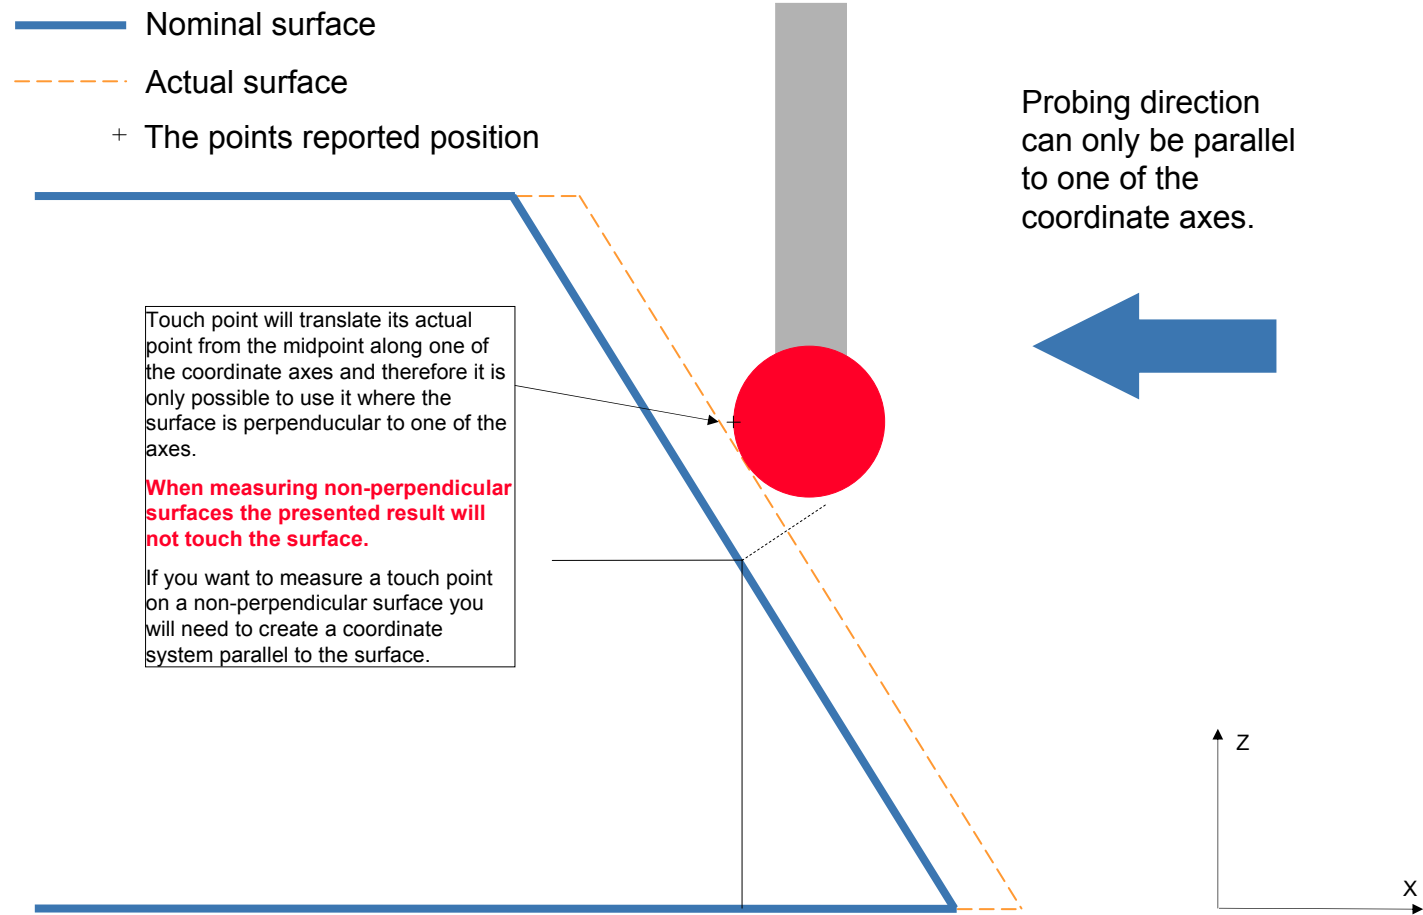

— Nominal surface
- - - Actual surface

Unfortunately the machine are not able to position accurate enough for the point to be probed at exactly along the normal. It will miss with a significant distance. How much it is depends on the machine and sensor.
The picture is exaggrated

Touch point

Mid point

Plane point

Space point

Net point

Cad Face Point

- Nominal surface
- - - Actual surface
- + The points reported position

Cad Face Point does not translate its value in any way. When the point is taken it finds the closest Cad-surface and does its radial compensation perpendicular to that surface. This means that you can take manual probings of a freeform surface without thinking about about the vector.

It is possible to take several probings for each point to form an average point. Each single point will be radially compensated individually according to the closest Cad-surface.

Observe.

1. You should always try to take the points as perpendicular to the surface as possible. When programming with Cad Face point you should use the Cad model to extract the correct vector.
2. The characteristic "True position" will most likely give an unwanted result for a Cad Face point. Since the nominal X,Y and Z will not be changed according to the model the result when evaluating to a points nominal values will be wrong
3. The characteristics "Space Point distance" and "Profile" will give the deviation from the Cad surface and thus give the correct result.
